

# Housing EDA

*David Gerard*

*2019-02-07*

Researchers were interested in predicting residential home sales prices in a Midwestern city as a function of various characteristics of the home and surrounding property. Data on 522 transactions were obtained for home sales during the year 2002. The 13 variables are

- **Price:** Sales price of residence (in dollars)
- **Area:** Finished area of residence (in square feet)
- **Bed:** Total number of bedrooms in residence
- **Bath:** Total number of bathrooms in residence
- **AC:** 1 = presence of air conditioning, 0 = absence of air conditioning
- **Garage:** Number of cars that a garage will hold
- **Pool:** 1 = presence of a pool, 0 = absence of a pool
- **Year:** Year property was originally constructed
- **Quality:** Index for quality of construction. **High**, **Medium**, or **Low**.
- **Style:** Categorical variable indicating architectural style
- **Lot:** Lot size (in square feet)
- **Highway:** 1 = highway adjacent, 0 = highway not adjacent.

The data are available in “estate.csv” at [https://dcgerard.github.io/stat\\_412\\_612/data/estate.csv](https://dcgerard.github.io/stat_412_612/data/estate.csv).

Perform an exploratory data analysis to come up with some hypotheses. Some suggested ways to focus your research:

- Which variables are categorical? Which are quantitative?
- What variables are marginally associated with price? Use plots and summary statistics.
- What variables are marginally associated with each other? Use plots and summary statistics.
- If a variable is marginally associated with price, are there some other variables that could explain that association? Use plots and summary statistics.
- Does there appear to be any discrete groupings of houses?
- Are there any unusual observations?
- What transformations should you perform to make associations more linear?
- What variables should be discretized (or have values aggregated) because there are too few values and/or the association seems discrete?
